Waterfall Method v Agile Development

The agile development method is software development method in which the software is developed in sprints. The developers quickly finish all requirements to get a base software that can later be built on in a future sprint. Each sprint is added on until the final product is complete. In a waterfall method, each step is done to absolute completion before moving onto the next and in the end there is a finished product. The main difference between the two is that an agile developed software tends to have several builds, betas, and alphas before reaching the final product.
